

Story-at-a-Glance

EECP is cost effective when compare to other modalities of treatment.

CABG carries high risk of procedural and post-operative complications.

During EECP treatment sessions, patient can able to go to work and other routine activities.

EECP is first option for Coronary Artery Disease to improve the quality of life and improve myocardial blood flow beyond blocked arteries.

All the treatment strategy for coronary artery disease, whether it is invasive or non-invasive, bypass or angioplasty or EECP or it is medical management, these strategies basic is to improve the blood flow to heart muscles across the blocked arteries. So if you want to increase the blood supply across the blocked arteries in a simple way, EECP is an only solution.

- EECP is absolutely a non-invasive treatment.
- It does not involve any invasive procedure and does not involve any injection.
- It is highly cost effective.

When compare with existing modalities of treatment like PTCA and CABG. It actually costs 1/4th of the cost of the bypass surgery and angioplasty. But it can provide the same relief in symptom and same improvement in quality of life. What a CABG and PTCA can offer. Since EECP is non-invasive it is does not involve any injury or complications or any adverse effects when compare to PTCA and CABG.

Even though invasive treatments are effective in certain group of patient, it also carries a high risk of procedural complication and post-operative complications. All this complications are very dread full. In certain condition CABG surgery may cause stroke. Sometimes it causes a reduction of memory loss and many times delay in wound healing may take place. It takes months for the patient to completely heal.

Here EECP absolutely a non – invasive does not have to involve in any injury. So patient can able to go to work every day after one hour treatment. So over all when compare to advantages of cardiac treatment, EECP provide improvement similar to what invasive surgery can offer. So as a physician I would recommend EECP as a first option for patient with coronary artery disease to improve their quality of life and improve myocardial blood flow beyond the blocked artery. If EECP may not able to provide symptomatic improvement, quality of life improvement and prevent recurrent hospitalization and then I may consider other invasive options. In our experience with optimal medical management and EECP in patient with stable condition more than 90% of patient may not need to go for an interventional procedure
