

## Story-at-a-Glance

EECP can be provided for patients who have established heart disease and also for patients who want to have better control over their cardiac risk factors like Diabetics and Hypertension.

EECP would be right treatment for those patients who don't want to undergo invasive procedures.

For high risk patients and heart failure patients EECP treatment would be a best and only non-invasive option.

### Non-surgical heart treatment (EECP) to avoid bypass surgery and angioplasty

Who can undergo vaso-meditech EECP treatment?

EECP can be provided for patient who has established heart diseases or patient who want to have better control over the cardiac risk factors, this risk factors includes diabetes, hypertension, hyperlipidemia and also patient who are not willing to undergo an angiogram and further intervention procedure. EECP act as a regular exercise it increase the blood flow to the heart muscle as what aggressive exercise can do. So it can also taken by patients who cannot able to do exercise because of arthritis or old age or they cannot exercise because of their symptoms.

Many times patients do an angiogram because the symptoms are not controlled by medical management. After the angiogram the patient are suggested either a bypass surgery or angioplasty and if patient is not willing for invasive and expensive therapy, EECP could be a good alternative, because EECP improves the blood supply across the blocked arteries like an exercise and benefits the patient. When the cardiologist, cardio thoracic surgeon looked at your angiogram they may say all the vessel cannot be grafted or stented in the sense if you have three or four lesions the interventional cardiologist or a cardio thoracic surgeons may give an opinion that only one or two vessel can be grafted or stented and other vessel can be left behind what we called as a partial re-vascularization. It is not a complete attempt to address all the obstructions only couple of obstructions are addressed and other obstructions are left behind. Rather than going for the bypass surgery and angioplasty, EECP could be a very effective and attractive alternative. Because it can improve the blood supply across all the

coronary artery rather than focusing on a single vessel. coronary artery rather than focusing on a single vessel.

And the other group of patient is after angiogram the interventional cardiologist may discuss with you and tell you that yours case is high risk for interventional procedure, high risk angioplasty in these type of situation also eecp could be a best alternative for this patient. Finally there is another group of patient which is increasing across the nation because of the prevalence of diabetic and hypertension and non-adherent to the medical management because these patients even after undergoing an bypass surgery and angioplasty because of their poor life style they may tend to get a graft occlusion or Restenosis bypass graft which they have put hasclosed or the stent they have put has closed. We call it as restenosis in the

theses case repeating the procedure whether it is bypass or angioplasty, carry a very high mortality or very high death rate. So in this group of patients, EECP would be a safe alternative to improve the blood circulation to the heart muscle without undergoing this expensive and high risk procedure.

There is another group of patients who we call as heart failure because of the myocardial infarction or heart attack. Patient will tend to get drastically reduced pumping function. Once it is reduced carrying out any interventional procedure whether it is bypass or angioplasty involves very high risk and mostly physicians or a interventional cardiologist would try to avoid this patient. Suggesting EECP treatment for this the patient would definitely improve the quality of life and walking distance. So eecp is absolutely a non-invasive option for all these group of patient and it can able to effectively relieve the symptom and put them back into their normal routine activity.
